Kojić, Momčilo, Sava Vrbničanin, Zora Dajić, Slavica Mrfat-Vukelić (2001): *Weed flora of natural grasslands in Serbia*. - Acta herbologica, Vol. 10, No.1, 1-22.

Meadow and pasture weed flora in Serbia is surveyed and ecological analysis provided. The acquired data show a very high participation of weed species in grassland areas. Weeds accounted for over 50% of overall floristic composition of the analysed meadow and pasture plant communities (48), which belong to the classes *Phragmitetea*, *Molinio-Arrhenatheretea*, *Festuco-Brometea*, *Festucetea vaginatae*, *Nardo-Callunetea* and *Juncetea trifidi*. The lowest participation of weeds was 50.7% in the class *Festuco-Brometea*, while the highest reached as much as 91.3% in the class *Phragmitetea*.

Viewed from the phytocoenological aspect, weed plants are equal with other (beneficial) coenobions in grassland areas. However, viewed from the aspect of grassland utilization they belong to an undesirable group of plants. Depending on the degree of harmfulness, grassland weeds may be differentiated into several groups: 1. plants of low forage value, consumed by livestock but only reluctantly (e.g. *Nardus stricta*); 2. prickly plants (with thorns, hooks and emergence growths) such as *Carduus sp.*, *Cirsium sp.*, *Ononis spinosa*, *Eryngium campestre*, etc., which may cause injury to the mouth, throat, stomach or intestines; and 3. poisonous species such as *Aristolochia clematitis*, *Atropa belladonna*, *Colchicum autumnale*, *Conium maculatum*, *Euphorbia sp.*, *Hyoscyamus niger*, *Veratrum album* and many others, which may

Corresponding author: Momčilo Kojić, Faculty of Agriculture, Nemanjina 6, 11080 Zemun-Belgrade, Yugoslavia

cause disorders of some sort in animals and even produce fatal result when consumed in large amounts.

Key words: meadow, pasture, weeds, flora

INTRODUCTION

Flora and vegetation of natural grasslands in Serbia are remarkably rich and diverse. This wealth comes as a result of many influences of edaphic, chorographic, hydrological and climatic specificities characterizing the local swamps, valleys, hills, mounts and high mountains that are habitats of numerous natural meadows and pastures. Speaking from the phytocoenological point of view, all plant species have equal status regarding their participation in the herbaceous type of vegetation characteristic of natural grasslands. However, considering the aspect of utilization of such grasslands, all coenobions could be divided into two basic groups:

1. Desirable (beneficial) species - plants with high forage value that are preferred by livestock, and
2. undesirable (unuseful or harmful) species - plants with low forage value, prickly and poisonous species mostly avoided by livestock on pastures (MRFAT-VUKELIĆ *et al.*, 1991; KOJIĆ *et al.*, 1993). This second category of grassland coenobions may be described as weeds of meadows and pastures, i.e. undesirable elements in meadow and pasture phytocoenoses. According to data presented by KOJIĆ *et al.* (2000), such species, and their lower taxa, participate with over 50% in natural grasslands in Serbia, considering all species forming their floristic composition.

A number of domestic researchers (MRFAT-VUKELIĆ *et al.*, 1991, 1996; KOJIĆ *et al.*, 1992, 1993, 1994; KOJIĆ and VRBNIČANIN, 1998) have committed their efforts to investigation of weeds in meadows and pastures, approaching the problems from different aspects (floristic, phytocoenological, ecophysiological, practical, etc.). Considering the huge importance of this category of plants in natural meadows, both from the semantic-phytocoenological aspect and the aspect of utilization of meadows and evaluation of their quality, the objective of this investigation was to put more light onto the problem of grassland weeds by way of a floristic analysis.

MATERIALS AND METHODS

Weed flora of natural meadows and pastures in Serbia was analysed based on 48 most widespread communities classified as: *Phragmitetea* (3 associations), *Molinio-Arrhenatheretea* (12), *Festuco-Brometea* (24), *Festucetea vaginatae* (1), *Nardo-Callunetea* (4) i *Juncetea trifidi* (4), which have been described by a number of authors. These analysed communities can be found at locations from the lowest to highest altitudes in Serbia, including swampy grounds.

Determination and categorization of weed species was performed according to ŠOŠTARIĆ-PISAČIĆ and KOVAČEVIĆ (1968), KLAPP (1986) and KOJIĆ *et al.* (2000).

Plant life-forms were determined based on literature including: RAUNKIAER (1934), ELLENBERG (1979) and BRAUN-BLANQUET (1964).

Floral elements were determined using the following literature sources: HORVAT *et al.*, (1974) and GAJIĆ (1984).

Ecological indices and indicators of habitat values for the most important environment factors - humidity (F), soil pH (R), nutrients (nitrogen) in soil (N), light (L) and temperature (T) - are given according to LANDOLT (1977) and KOJIĆ *et al.*, (1997).

RESULTS AND DISCUSSION

A total of 549 weed species was found in 48 most widespread associations in natural grasslands in Serbia (Table 1). Such a high number of undesirable plant species on meadows and pastures can be explained, according to STAHLIN (1977), CAPUTA (1984) and KLAPP (1986), as the result of: excessive soil moisturization, which makes soil insufficiently aired; impoverishment of soil, which raises soil pH; shading; overly fine soil texture; damage caused by frost and erosion; and excessive mowing and pasture. In other words, deterioration of conditions existing on a habitat allows an expansion of species with high compatibility, and those are precisely the weed species. Table 1 shows that this large number of weed species falls into 231 genera and 52 families. Regarding the number of weed species, the most prominent are the families: *Asteraceae* (85 korovskih vrsta), *Poaceae* (44), *Scrophulariaceae* (37), *Caryophyllaceae* (36), *Lamiaceae* (34), *Rosaceae* (24), *Cyperaceae* (22) and *Fabaceae* (19).

Biodiversity of weeds on natural grasslands appears even greater when infraspecies diversity is considered. The total number of infraspecies taxa is 945, including 249 subspecies, 347 varieties and 349 forms.

Table 2. The spectrum of life forms in Serbia's grassland weed flora

Life forms	No. of species	%
Hemikriptofite (H) / Hemicryptophytes	281	50.57
Geofite (G) / Geophytes	86	15.46
Terofite (T) / Therophytes	82	14.91
Terohemikriptofite (TH) / Therohemicryptophytes	41	7.73
Zeljaste hamefite (zc) / Herbaceous chameophytes	27	4.84
Drvenaste hamefite (dc) / Weedy chameophytes	21	4.33
Nanofanerofite (nP) / Nanopharenophytes	9	1.81
Fanerofite (P) / Phanerophytes	2	0.32
Ukupno / Total	549	100

Total	549	100.00

Besides the high taxonomic diversity of weeds in meadows and pastures, ecological diversity is highly pronounced and reflects in a large number of life forms. A total of 8 life forms was determined: hemicryptophytes, geophytes, therophytes, therohemicryptophytes, herbaceous chameophytes, weedy chameophytes, nanopharenophytes, and phanerophytes (Table 2).

In floro-geographic respect, weeds of meadows and pastures are considerably diverse. As many as 25 geo-elements are represented in the weed flora of natural grasslands. The most widespread and most important are the following geo-elements: Eurasian, Sub-Middle-European, Sub-Mediterranean, Circumpolar, Sub-Pontic and Central-European floral elements (Table 3).

Table 4. Participation of weed species of particular categories

Class	Total	No. of species	Very poisonous species	Slightly poisonous species	Worthless species
<i>Phragmitetea</i>	interval	56.8-91.3	4.3	11.4-15.8	45.4-73.9
	x=	72.2	4.3	13.4	59.3
<i>Molinio-Arrhenatheretea</i>	interval	56.9-75.6	1.1-5.0	4.8-19.7	43.4-58.5
	x=	67.6	3.1	13.2	51.5
<i>Festuco-Brometea</i>	interval	50.7-70.0	0.9-5.0	7.7-20.0	35.0-53.2
	x=	60.3	3.8	12.8	45.7
<i>Festucetea vaginatae</i>	interval	74.6	3.2	11.1	60.3
	x=	74.6	3.2	11.1	60.3
<i>Nardo-Callunetea</i>	interval	58.7-64.4	1.4-4.8	11.9-15.1	42.9-47.9
	x=	60.3	2.1	13.1	45.2
<i>Juncetea trifidi</i>	interval	58.3-71.1	1.6-3.4	5.0-13.5	53.3-55.7
	x=	65.5	1.7	9.5	54.3

Such geographic structure of grassland weeds indicates a somewhat continental character of the analysed flora, which agrees with the general character of the entire herbaceous flora and vegetation of the Serbian region (JANKOVIĆ, 1985). The highest number of species was found in swampy grassland communities of the class *Phragmitetea* - 72.2%, while the lowest number belonged to the classes *Festuco-Brometea* and *Nardo-Callunetea* - 60.3%. Participation of some weed categories (very poisonous, slightly poisonous and worthless) varies and is shown in Table 4.

Especially interesting is the group of very poisonous weeds, including 23 species (4.19%) found in this investigation. The highest number of species (11) belong to the family *Euphorbiaceae*, genus *Euphorbia* (spurges). Following on the list are species of the family *Equisetaceae* (3 species of the genus *Equisetum*) and as many species of the family *Liliaceae*. These are followed by two species each of the families *Ranunculaceae* and *Scrophulariaceae* and one each poisonous weed species of the families *Polypodiaceae* and *Aristolochiaceae*. The most poisonous and consequently most dangerous weeds of natural grasslands in Serbia are: *Aristolochia clematitis*, *Equisetum sp.*, *Euphorbia sp.*, *Colchicum autumnale*, *Veratrum album*, *Digitalis lanata*, *Ranunculus sp.*, *Pteridium aquilinum*, *Rhinanthus sp.*, etc.

Weeds of natural grasslands require special attention as they may cause considerable difficulties and problems when consumed in any way by grazing livestock or humans. These justified reasons have inspired us to chose to focus our future research on very poisonous weeds of natural grasslands of Serbia.

CONCLUSION

Based on our analysis of 48 meadow and pasture plant communities across Serbia, the following conclusions are suggested:

- weeds on natural grasslands participate significantly in the floristic composition of meadow and pasture phytocoenoses, ranging between 50.7% and as much as 91.3% of the total number of species;
- a total of 549 weed species belonging to 231 genera and 52 families were found;
 - the number of infraspecies taxa was found to be very high: 249 subspecies, 347 varieties and 349 forms;
 - hemicryptophytes (56.57%) are the largest category of the 8 weed life forms found;
 - grassland weeds are characterised by high floro-geographic diversity
- 25 geo-elements were found, including predominantly Eurasian, Sub-Middle-European, Sub-Mediterranean, Circumpolar and Sub-Eurasian;
 - poisonous plants, the most dangerous category of weeds on grasslands, account for 4% of all species.

Due to such high participation of weed species in the total flora of meadows and pastures in Serbia, this problem requires more attention in future research, both from the floristic and phytocoenological aspect, and from the practical aspect, in the sense of taking certain steps to control and suppress them.

I z v o d

U radu je analizirano 48 travnjačkih zajednica Srbije. Ispitivane su i močvarne i vlažne livade, submontane, montane i alpske travnjačke fitocenoze.

Utvrđeno je ukupno 549 vrsta na travnjačkim staništima korova. Ove korovske vrste klasifikovane su u 231 rod iz 52 familije. Sledeće familije su naročito bogate u pogledu broja korovskih vrsta: *Asteraceae* (85 korovskih vrsta), *Poaceae* (44), *Scrophulariaceae* (37), *Caryophyllaceae* (36), *Lamiaceae* (34), *Rosaceae* (24), *Cyperaceae* (22) i *Fabaceae* (19).

Korovske vrste pokazuju veliku infraspecijsku raznovrstnost i uključuju 249 podvrsta, 347 varijeteta i 349 formi. Što se tiče biološkog spektra, dominiraju hemikriptofite (50,57%). Horološka analiza pokazuje da u korovskoj flori travnjaka Srbije učestvuje 25 različitih geoelemenata, od čega više od 50% pripada flornim elementima velikih površina rasprostranjenja: evroazijskom, subevroazijskom, srednje-evropskom i kosmopolitskom.

Procenat prisustva korovskih vrsta je od 50,7% (u klasi *Festuco-Brometea*) do 91,3% (u klasi *Phragmitetea*).
